"POLYPROPYLENE FIBRES SUITABLE FOR THERMAL BONDED NON-WOVEN FABRICS"

The present invention relates to thermal bondable fibres comprising propylene polymer compositions, thermally bonded non-woven fabrics obtained from the said fibres and polypropylene compositions for the production of the said fibres.

The definition of "fibres" includes also products similar to fibres, such as fibrils and cut filaments (staple fibres).

Fibres of certain thermoplastic materials are used widely in the manufacturing of thermally bonded products, such as non-woven fabrics, by various processes. Said processes are mainly staple carding/calendering, through air-bonded, spunbonding, melt-blown, and any combination of them for composite structures of non-woven fabrics.

Thermal bonding staple by long and short spinning with carding/calendering as well as spun bond is one of the main technologies applied to produce hygiene non-woven fabrics. Thermal bonding staple production technology has a number of advantages, such as less investment costs and capability of producing softer/better handling non-woven fabrics with a very homogeneous aspect.

A fundamental requirement of polyolefin fibres for thermal bonded non-woven fabrics is that fibres must bond to each other by means of the joint action of temperature and pressure on which the hot calendering process is based.

A drawback of such technology, which requires a two-stage process (staple production and carding/calendering) with higher variable costs, is the production of non-woven fabrics with lower tenacity in cross direction and shows limitations in the minimum non-woven-fabric weight reachable due to the carding constraints. The cross-directional strength of the thermal bonded non-woven fabrics is mainly affected by the high orientation induced on the fibres along machine direction during carding/calendering process.

There is a need to produce thermal bondable fibres that are not so affected by the said drawback and as a result it is found that specified propylene polymers are much superior in the mechanical properties to usual propylene polymers for fibres.

There have already been made various attempts to improve the thermal bondability (i.e. the bond strength) of polyolefin fibres and/or the calendering speed of fibres. For instance US patent 4,211,819 describes heat-melt adhesive fibres obtained by spinning a crystalline (propylene-co-ethylene-co-1-butene)polymer. Such fibres having a lower heat-melting

adhesive temperature are used as binder material only, therefore the mechanical properties are conferred by other materials. In fact, when non-woven fabrics are prepared in the examples, the said fibres are mixed with rayon fibres before calendering.

The applicant has now found that thanks to particular olefin copolymers and olefin copolymer blends fibres having an improved thermal bondability associated with a good balance of mechanical properties can be provided.

In particular, the fibres of the present invention are capable of bonding to each other at lower temperatures than the known polypropylene fibres.

Another advantage is that the fibres of the present invention show higher tenacity values but without an evident decrease of the values of elongation at break.

A further advantage of the fibres of the present invention is that the said fibres are capable of bonding tenaciously even if the fibres have a relatively low melt flow ratio. In fact, it has been surprisingly found that the fibres of the present invention do not necessarily require the formation of skin-core structures to achieve high levels of bond strength.

The applicant has also found that thanks to the fibres of the present invention it can be achieved thermal bonded non-woven fabrics having improved physical properties and loftiness in comparison with thermal bonded non-woven fabrics made of propylene homopolymers and copolymers with similar melt flow rate (MFR). In particular, non-woven fabrics of the present invention have improved strength properties, more particularly higher cross-directional tenacity and higher bonding force.

A further advantage is that non-woven fabrics of the present invention are produced at lower thermal bonding temperature maintaining the same calendering speed or at the same calendering temperature with higher calendering speed.

Therefore the present invention provides thermal bondable fibres consisting of a propylene polymer composition having a MFR "L" value from 4 to 20 g/10 min, preferably from 6 to 15 g/10 min, and comprising a polymer component selected from:

- i) a crystalline propylene random polymer containing at least 0.8% by weight of ethylene, preferably 0.8-5 wt%, and optionally one or more C₄-C₁₀ α -olefins, and having a melting temperature of 155° C or higher, a content of fraction soluble in xylene at room temperature (about 25° C) lower than 5% by weight, a value of the ratio of the polymer fraction collected at the temperature range from 25° to 95° C by temperature rising

elution fractionation with xylene (TREF) to the xylene-soluble fraction, higher than 8; and

ii) a crystalline propylene polymer blend containing at least 0.64 wt% of the ethylene recurring unit and comprising (percent by weight):

I) 20-80%, preferably from 30-70%, of a crystalline propylene homopolymer and/or crystalline propylene random copolymer containing up to 1.5% by weight of ethylene; and

II) 20-80%, preferably from 30-70%, of a crystalline random copolymer selected from:

IIa) a copolymer of propylene with 0.8 to 9% by weight of ethylene; provided that the difference in the ethylene content between polymer (I) and polymer (IIa) be at least 0.8 percentage unit, preferably 1 percentage unit, more preferably 2 percentage units, with respect to the weight of the (co)polymer concerned;

IIb) a copolymer of propylene with 1.5 to 18% by weight of a C₄-C₁₀ α -olefin and optionally ethylene; provided that the difference in the comonomer content between polymer (I) and polymer (IIb) be at least 1.5 percentage units, preferably 2 percentage units, with respect to the weight of the (co)polymer concerned; and

IIc) a mixture of copolymer (IIa) and copolymer (IIb).

Blend (ii) has a melting temperature of 153° C or higher and a content of fraction soluble in xylene at room temperature lower than 10% by weight, preferably lower than 9% by weight.

The preferred polymeric component is polymeric blend (ii) containing at least 0.64 wt% of ethylene recurring unit and having the following composition (percent by weight):

I) 20-80%, preferably from 30-70%, of a crystalline propylene homopolymer and/or crystalline propylene random copolymer containing up to 1.5% by weight of ethylene; and

II) 20-80%, preferably from 30-70%, of a crystalline random copolymer selected from:

IIa) a copolymer of propylene with 0.8 to 5% by weight of ethylene; provided that the difference in the ethylene content between polymer (I) and polymer (IIa) be at least 0.8 percentage unit, preferably 1 percentage unit, more preferably 2 percentage units, with respect to the weight of the (co)polymer concerned;

IIb) a copolymer of propylene with 1.5 to 12% by weight of a C₄-C₁₀ α -olefin and optionally ethylene; provided that the difference in the comonomer content between

polymer (I) and polymer (IIb) be at least 1.5 percentage units, preferably 2 percentage units, with respect to the weight of the (co)polymer concerned; and

IIc) a mixture of copolymer (IIa) and copolymer (IIb).

Typically, polymer blend (ii) has a value of melting temperature of at 155° C or higher, a content of fraction soluble in xylene at room temperature (about 25° C) lower than 5% by weight, preferably lower than 4% by weight, and a value of the ratio of the polymer fraction collected at the temperature range from 25° to 95° C by TREF to the xylene-soluble fraction higher than 8.

More preferably, blend polymer (I) is the propylene homopolymer and copolymer (II) is the ethylene-propylene copolymer.

Typically, the fibres according to the present invention have a value of tenacity higher than 20 cN/tex, preferably higher than 21 cN/tex, with standard throughput and winding speed during the production of staple fibres by long and short spinning technology.

The elongation at break shown by the fibres of the present invention is typically higher than 200%, preferably at least 220%, with standard throughput and winding speed during the production of staple fibres by long and short spinning technology.

The fibres according to the present invention generally have a value of bonding force at 150° C of at least 300 cN, preferably at least 350 cN. The said bonding force values are achieved even with a fibre having a MFR value as low as 20 g/10 min as obtained from a Leonard spinning line as described in the example. For example, fibres having a MFR value ranging from 20 to 50 g/10 min can have a bonding force value from 300 to 800 cN.

The fibres produced by long and short spinning technology, according to the present invention have preferably a titre ranging from 1 to 8 dtex, preferably 1.5 to 8 dtex.

When only ethylene is present as the comonomer in random copolymer (i), the ethylene content is generally within 0.8 and 2% by weight with respect to the weight of the polymer.

When C₄-C₁₀ α -olefins are also present, their content preferably ranges from 1 and 6 wt% by weight with respect to the weight of the copolymer.

When ethylene also is present as the comonomer in random copolymer (IIb), the ethylene content is generally within 1% by weight with respect to the weight of the polymer.

The above crystalline polymers have a stereoregularity of the isotactic type.

Preferably the composition of the present invention has a Polydispersity Index (PI) value from 3 to 5, more preferably from 3 to 4.5.

The MFR values of the two propylene polymers constituting polymer blend (ii) can be similar or different. In a particular embodiment of the present invention the MFR value of propylene polymer (I) is lower than that of propylene random copolymer (II).

The C₄-C₁₀ α-olefins that may be present as comonomers in the polymer composition according to the present invention are represented by the formula CH₂=CHR, wherein R is an alkyl radical, linear or branched, with 2-8 carbon atoms or an aryl (in particular phenyl) radical. Examples of said C₄-C₁₀ α-olefins are 1-butene, 1-pentene, 1-hexene, 4-methyl-1-pentene and 1-octene. Particularly preferred is 1-butene.

Therefore, a further embodiment of the present invention is represented by a crystalline propylene polymer blend that is suitable to prepare fibres.

The said polymer blend has a MFR "L" value from 4 to 20 g/10 min, preferably from 6 to 15 g/10 min, an ethylene content of at least 0.64 wt% and comprising (percent by weight):

- I) 20-80%, preferably from 30-70%, of a crystalline propylene homopolymer or crystalline propylene random copolymer containing up to 1.5% by weight of ethylene; and
- II) 20-80%, preferably from 30-70%, of a crystalline random copolymer of propylene with higher than 5 to 9% of ethylene.

The said blend has a value of melting temperature of 153° C or higher and a content of fraction soluble in xylene at room temperature (about 25° C) lower than 10%, preferably lower than 5% by weight, more preferably lower than 4% by weight.

The above crystalline polymers have a stereoregularity of the isotactic type.

Preferably the blend of the present invention has a Polydispersity Index (PI) value from 3 to 5, more preferably from 3 to 4.5.

The MFR values of the two propylene polymers constituting polymer blend can be similar or different. In a particular embodiment of the present invention the MFR value of propylene polymer (I) is lower than that of propylene random copolymer (II).

The propylene polymer material according to the present invention is produced with conventional processes. For example, the polymer material can be prepared by polymerising the monomers in one or more consecutive or parallel stages.

When the polymer material is a blend, it is preferably a chemical blend prepared by polymerising the monomers in two or more consecutive stages. In such a case, the polymerisation process is carried out in at least two separate subsequent stages, wherein in at least two polymerisation stages the relevant monomers are polymerised to form polymer (I)

and in the other stage(s) the relevant monomers are polymerised to form polymer (II), operating in each stage, except the first step, in the presence of the polymer formed and the catalyst used in the preceding stage. The molecular weight regulator (preferably hydrogen) is fed in such amounts as to obtain an MFR L value for the composition of from 4 to 20 g/10 min, preferably from 6 to 15 g/10 min. The catalyst is added only in the first stage; however its activity is such that it is still active for all the subsequent stages. The order in which the polymers of the blends are prepared is not critical.

The regulation of the molecular weight is carried out by using known regulators, hydrogen in particular.

By properly dosing the concentration of the molecular weight regulator in the relevant steps, the previously described MFR values are obtained.

The whole polymerisation process can be continuous or batch according to known techniques and operating in liquid phase, in the presence or not of inert diluent, or in gas phase, or by mixed liquid-gas techniques.

Reaction time, pressure and temperature relative to the two steps are not critical, however it is best if the temperature is from 20° to 100° C. The pressure can be atmospheric or higher.

Alternatively, it is also possible to employ a process for the catalytic polymerisation in the gas-phase carried out in at least two interconnected polymerisation zones, the process comprising feeding one or more monomers to said polymerisation zones in the presence of catalyst under reaction conditions and collecting the polymer product from said polymerisation zones, in which process the growing polymer particles flow upward through one of said polymerisation zones (riser) under fast fluidisation conditions, leave said riser and enter another polymerisation zone (downcomer) through which they flow downward under the action of gravity, leave said downcomer and are reintroduced into the riser, thus establishing a circulation of polymer between the riser and the downcomer, the process being optionally characterised in that:

- means are provided which are capable of totally or partially preventing the gas mixture present in the riser from entering the downcomer, and
- a gas and/or liquid mixture having a composition different from the gas mixture present in the riser is introduced into the downcomer.

Such polymerisation process is illustrated in WO 00/02929.

According to a particularly advantageous embodiment of this process, the introduction into the downcomer of the said gas and/or liquid mixture having a composition different from the gas mixture present in the riser is effective in preventing the latter mixture from entering the downcomer.

The polymerisation is preferably carried out in the presence of stereospecific Ziegler-Natta catalysts. An essential component of said catalysts is a solid catalyst component comprising a titanium compound having at least one titanium-halogen bond, and an electron-donor compound, both supported on a magnesium halide in active form. Another essential component (co-catalyst) is an organoaluminium compound, such as an aluminium alkyl compound. An external donor is optionally added to the organoaluminium compound.

The catalysts generally used in the process of the invention are capable of producing polypropylene with an Isotacticity Index greater than 90%, preferably greater than 95%.

Catalysts having the above mentioned characteristics are well known in the patent literature; particularly advantageous are the catalysts described in US patent 4,399,054 and European patent 45977. Other examples can be found in US patent 4,472,524.

The solid catalyst components used in said catalysts comprise, as electron-donors (internal donors), compounds selected from the group consisting of ethers, ketones, lactones, succinates, compounds containing N, P and/or S atoms, and esters of mono- and dicarboxylic acids.

Particularly suitable electron-donor compounds are non-extractable succinates; particularly preferred are the succinates of formula (I) below

in which the radicals R_1 and R_2 , equal to, or different from, each other are a C_1 - C_{20} linear or branched alkyl, alkenyl, cycloalkyl, aryl, arylalkyl or alkylaryl group, optionally containing heteroatoms; and the radicals R_3 and R_4 equal to, or different from, each other, are C_1 - C_{20} alkyl, cycloalkyl, aryl, arylalkyl or alkylaryl group, optionally containing heteroatoms with the proviso that at least one of them is a branched alkyl; said compounds being, with respect

to the two asymmetric carbon atoms identified in the structure of formula (I), stereoisomers of the type (S,R) or (R,S) that are present in pure forms or in mixtures.

R₁ and R₂ are preferably C₁-C₈ alkyl, cycloalkyl, aryl, arylalkyl and alkylaryl groups.

Particularly preferred are the compounds in which R₁ and R₂ are selected from primary alkyls and in particular branched primary alkyls. Examples of suitable R₁ and R₂ groups are methyl, ethyl, n-propyl, n-butyl, isobutyl, neopentyl, 2-ethylhexyl. Particularly preferred are ethyl, isobutyl, and neopentyl.

Particularly preferred are the compounds in which the R₃ and/or R₄ radicals are secondary alkyls like isopropyl, sec-butyl, 2-pentyl, 3-pentyl or cycloalkyls like cyclohexyl, cyclopentyl, cyclohexylmethyl.

Examples of the above-mentioned compounds are the (S,R) (S,R) forms pure or in mixture, optionally in racemic form, of diethyl 2,3-bis(trimethylsilyl)succinate, diethyl 2,3-bis(2-ethylbutyl)succinate, diethyl 2,3-dibenzylsuccinate, diethyl 2,3-diisopropylsuccinate, diisobutyl 2,3-diisopropylsuccinate, diethyl 2,3-bis(cyclohexylmethyl)succinate, diethyl 2,3-diisobutylsuccinate, diethyl 2,3-dineopentylsuccinate, diethyl 2,3-dicyclopentylsuccinate, diethyl 2,3-dicyclohexylsuccinate.

Other suitable electron-donor compounds are 1,3-diethers of formula:

wherein R^I and R^{II} are the same or different and are C₁-C₁₈ alkyl, C₃-C₁₈ cycloalkyl or C₇-C₁₈ aryl radicals; R^{III} and R^{IV} are the same or different and are C₁-C₄ alkyl radicals; or are the 1,3-diethers in which the carbon atom in position 2 belongs to a cyclic or polycyclic structure made up of 5, 6, or 7 carbon atoms, or of 5-n or 6-n' carbon atoms, and respectively n nitrogen atoms and n' heteroatoms selected from the group consisting of N, O, S and Si, where n is 1 or 2 and n' is 1, 2, or 3, said structure containing two or three unsaturations (cyclopolyenic structure), and optionally being condensed with other cyclic structures, or substituted with one or more substituents selected from the group consisting of linear or branched alkyl radicals; cycloalkyl, aryl, aralkyl, alkaryl radicals and halogens, or being condensed with other cyclic structures and substituted with one or more of the above mentioned substituents that can also be bonded to the condensed cyclic structures; one or more of the above mentioned alkyl, cycloalkyl, aryl, aralkyl, or alkaryl radicals and the

condensed cyclic structures optionally containing one or more heteroatoms as substitutes for carbon or hydrogen atoms, or both.

Ethers of this type are described in published European patent applications 361493 and 728769.

Representative examples of said dieters are 2-methyl-2-isopropyl-1,3-dimethoxypropane, 2,2-diisobutyl-1,3-dimethoxypropane, 2-isopropyl-2-cyclopentyl-1,3-dimethoxypropane, 2-isopropyl-2-isoamyl-1,3-dimethoxypropane, 9,9-bis (methoxymethyl) fluorene.

Other suitable electron-donor compounds are phthalic acid esters; such as diisobutyl, dioctyl, diphenyl and benzylbutyl phthalate.

The preparation of the above mentioned catalyst components is carried out according to various methods.

For example, a $\text{MgCl}_2 \cdot n\text{ROH}$ adduct (in particular in the form of spheroidal particles) wherein n is generally from 1 to 3 and ROH is ethanol, butanol or isobutanol, is reacted with an excess of TiCl_4 containing the electron-donor compound. The reaction temperature is generally from 80° to 120°C . The solid is then isolated and reacted once more with TiCl_4 , in the presence or absence of the electron-donor compound, after which it is separated and washed with aliquots of a hydrocarbon until all chlorine ions have disappeared.

In the solid catalyst component the titanium compound, expressed as Ti, is generally present in an amount from 0.5 to 10% by weight. The quantity of electron-donor compound which remains fixed on the solid catalyst component generally is 5 to 20% by moles with respect to the magnesium dihalide.

The titanium compounds which can be used for the preparation of the solid catalyst component are the halides and the halogen alcoholates of titanium. Titanium tetrachloride is the preferred compound.

The reactions described above result in the formation of a magnesium halide in active form. Other reactions are known in the literature, which cause the formation of magnesium halide in active form starting from magnesium compounds other than halides, such as magnesium carboxylates.

The active form of magnesium halide in the solid catalyst component can be recognized by the fact that in the X-ray spectrum of the catalyst component the maximum intensity reflection appearing in the spectrum of the nonactivated magnesium halide (having a surface area smaller than $3 \text{ m}^2/\text{g}$) is no longer present, but in its place there is a halo with the

maximum intensity shifted with respect to the position of the maximum intensity reflection of the nonactivated magnesium dihalide, or by the fact that the maximum intensity reflection shows a width at half-peak at least 30% greater than the one of the maximum intensity reflection which appears in the spectrum of the nonactivated magnesium halide. The most active forms are those where the above mentioned halo appears in the X-ray spectrum of the solid catalyst component.

Among magnesium halides, the magnesium chloride is preferred. In the case of the most active forms of magnesium chloride, the X-ray spectrum of the solid catalyst component shows a halo instead of the reflection which in the spectrum of the nonactivated chloride appears at 2.56 Å.

The Al-alkyl compounds used as co-catalysts comprise the Al-trialkyls, such as Al-triethyl, Al-triisobutyl, Al-tri-n-butyl, and linear or cyclic Al-alkyl compounds containing two or more Al atoms bonded to each other by way of O or N atoms, or SO₄ or SO₃ groups.

The Al-alkyl compound is generally used in such a quantity that the Al/Ti ratio be from 1 to 1000.

The electron-donor compounds that can be used as external donors include aromatic acid esters such as alkyl benzoates, and in particular silicon compounds containing at least one Si-OR bond, where R is a hydrocarbon radical.

Examples of silicon compounds are (tert-butyl)₂Si(OCH₃)₂, (cyclohexyl)(methyl) Si(OCH₃)₂, (phenyl)₂Si(OCH₃)₂ and (cyclopentyl)₂Si(OCH₃)₂.

Also 1,3-diethers having the formulae described above can also be used advantageously. If the internal donor is one of these diethers, the external donors can be omitted.

In particular, even if many other combinations of the previously said catalyst components may allow to obtain polymers and polymer compositions having the previously said features 1) and 2), the random copolymers are preferably prepared by using catalysts containing a phthalate as inside donor and (cyclopentyl)₂Si(OCH₃)₂ as external donor, or the said 1,3-diethers as inside donors and (cyclopentyl)₂Si(OCH₃)₂ as external donor.

Prior to the polymerisation process, the catalysts can be precontacted with small quantities of olefins (prepolymerisation), thus improving both the performance of the catalysts and the morphology of the polymers. Prepolymerisation is carried out maintaining the catalysts in suspension in a hydrocarbon solvent (hexane or heptane, for example) and polymerising at a temperature from ambient to 60°C for a time sufficient to produce quantities of polymer

from 0.5 to 3 times the weight of the solid catalyst component. It can also be carried out in liquid propylene, at the temperature conditions indicated above, producing quantities of polymer that can reach up to 1000 g per g of catalyst component.

The fibres of the present invention can contain formulations of stabilizers suited for obtaining a skin-core structure (skin-core stabilization) typical for thermal bonding staple fiber (i.e. for hygiene applications), or a highly stabilizing formulation, typical for staple fiber (i.e. geotextile applications). In the latter case, a superior resistance to aging is achieved, for durable non-wovens.

Preferred examples of skin-core stabilizations are those comprising one or more of the following stabilizers (percent by weight with respect to the total weight of polymer and stabilizers):

- a) from 0.01% to 0.5% of one or more organic phosphites and/or phosphonites;
 - b) from 0.005% to 0.5% of one or more HALS (Hindered Amine Light Stabilizer);
- and optionally one or more phenolic antioxidants in amounts not higher than 0.02%.

Specific examples of phosphites are:

tris (2,4-di-tert-butylphenyl) phosphite marketed by CIBA GEIGY under the trademark Irgafos® 168; distearyl pentaerythritol diphosphite marketed by BORG-WARNER CHEMICAL under the trademark Weston® 618; 4,4'-butylidene bis (3-methyl-6-tert-butylphenyl-di-tridecyl) phosphite marketed by ADEKA ARGUS CHEMICAL under the trademark Mark P®; tris (monononyl phenyl) phosphite; bis (2,4-di-tert-butyl) pentaerythritol diphosphite, marketed by BORG-WARNER CHEMICAL under the trademark Ultrinox® 626.

A preferred example of phosphonites is the tetrakis (2,4-di-tert-butylphenyl) 4,4'-diphenylilenediphosphonite, on which Sandostab® P-EPQ, marketed by Sandoz, is based.

The HALS are monomeric or oligomeric compounds containing in the molecule one or more substituted amine, preferably piperidine, groups.

Specific examples of HALS containing substituted piperidine groups are poly{[6-(1,1,3,3-tetramethylbutyl)-imine]-1,3,5-triazine-2,4-diol}[2-(2,2,6,6-tetramethylpiperidyl)amine] hexamethylene-[4-(2,2,6,6 tetramethylpiperidyl)imine] under the trademark Chimassorb® 944, poly(N- beta -hydroxymethyl-2,2,6,6-tetramethyl-4-hydroxy-piperidyl succinate) under the trademark Tinuvin® 622, bis(2,2,6,6-tetramethyl-4-piperidyl)sebacate under the trademark Tinuvin® 770, poly[hexamethylenedi(4-amino-2,2,6,6-tetramethyl)piperidine]

under the trademark Spinuvox® A-36, all marketed by Ciba-Geigy, bis(1,2,2,6,6-pentamethyl-4-piperidyl) sebacate under the trademark Tinuvin® 292 and bis(1,2,2,6,6-pentamethyl-4-piperidinyl 2-n-butyl(3,5-di-tert-butyl-4-hydroxybenzyl)malonate under the trademark Tinuvin® 144.

Another compound is 1,6-hexanediamine, N,N'-bis(2,2,6,6-tetramethyl-4-piperidinyl)-, polymer with 2,4-dichloro-6-84-morpholinyl-1,3,5-triazine marketed by American CYANAMID under the trademark Cyasorb® UV 3346.

Examples of phenolic antioxidants are: tris (4-tert-butyl-3-hydroxy-2,6-dimethylbenzyl)-s-triazine-2,4,6-(1H, 3H, 5H)-trione, marketed by American CYANAMID under the trademark Cyanox® 1790; calcium bi [monoethyl (3,5-di-tert-butyl-4-hydroxy-benzyl) phosphonate]; 1,3,5-tris (3,5-di-tert-butyl-4-hydroxybenzyl)-s-triazine-2,4,6 (1H, 3H, 5H) trione; 1,3,5-trimethyl-2,4,6-tris (3,5-di-tert-butyl-4-hydroxybenzyl) benzene; pentaerythrityl-tetrakis [3-(3,5-di-tert-butyl-4-hydroxyphenyl) propionate]; octadecyl 3-(3,5-di-tert-butyl-4-hydroxyphenyl)-propionate, marketed by CIBA GEIGY under the trademarks Irganox® 1425; Irganox® 3114; Irganox® 1330; Irganox® 1010; Irganox® 1076 respectively; 2,6-dimethyl-3-hydroxy-4-tert-butyl benzyl abietate.

Illustrative examples of skin-core stabilizations are given in EP-A-391 438.

Preferred examples of highly stabilizing formulations are those containing more than 0.02%, in particular from 0.04 to 0.2% by weight (with respect to the total weight of polymer and stabilizers) of one or more antioxidants, like, for example, phenolic antioxidants.

The above stabilizers can be added to the polymer by means of pelletization or surface coating, or they can be mechanically mixed with the polymer.

Moreover, the fibres of the present invention can contain other additives commonly employed in the art, like anti-slip agents, antistatic agents, flame retardants, fillers, nucleating agents, pigments, anti-soiling agents, photosensitizers.

The fibres of the present invention can be prepared by way of any known melt spin process. In particular, they can be prepared in form of staple fibres, by using both long-spinning and short-spinning apparatuses.

The long-spinning apparatuses normally comprise a first spinning section where the fibres are extruded and air-cooled in a quenching column at a relatively high spinning speed. Subsequently, these fibres go to the finishing step, during which they are drawn, crimped-bulked and cut. Generally, the above mentioned finishing step is carried out separately with

respect to the spinning, in a specific section where the fibre rovings are gathered into one single big roving. Said big roving is then sent to drawing, crimping-bulking and cutting apparatuses which operate at a speed ranging from 100 to 200 m/min.

In other types of long-spinning apparatuses the above mentioned finishing steps are carried out in sequence with the spinning step. In this case the fibres go directly from the gathering to the drawing rollers, where they are drawn.

The process conditions generally adopted when using the long-spinning apparatuses are the following:

- output per hole: greater than 0.1 g/min, preferably from 0.15 to 1 g/min, more preferably from 0.2 to 0.5 g/min;
- take up speed: equal to or higher than 500 m/min, preferably from 500 to 3500 m/min, more preferably from 600 to 2000 m/min;
- space where the fibres cool off and solidify after exiting the die: greater than 0.50 m.

Moreover, it is preferable that the draw ratio be from 1.1 to 4.

For further details on the long-spinning apparatuses reference is made to Friedelm Hauser "Plastics Extrusion Technology", Hauser Publishers, 1988, chapter 17.

The short-spinning apparatuses allow for a continuous operation, since the spinning speed is compatible with the drawing, crimping and cutting speeds.

The process conditions which are best suited to be used according to the present invention using short-spinning apparatuses are the following. The output per hole ranges from 0.005 to 0.18 g/min, preferably from 0.008 to 0.07 g/min, more preferably from 0.01 to 0.03 g/min. The take up speed ranges from 30 to 500 m/min, preferably from 40 to 250 m/min, more preferably from 50 to 100 m/min. The draw ratios range from 1.1 to 3.5, preferably from 1.2 to 2.5. Moreover, the fibre cooling and solidification space at the output of the die (cooling space) is preferably greater than 2 mm, more preferably greater than 10 mm, in particular from 10 to 350 mm. Said cooling is generally induced by an air jet or flow.

For further details on the short-spinning apparatuses reference is made to M. Ahmed, "Polypropylene fibres science and technology", Elsevier Scientific Publishing Company (1982) pages 344-346.

The spinning temperature for the above long-spinning and short-spinning apparatuses generally ranges from 220° to 340° C, preferably from 250° to 300° C. In particular, the

extruding temperature can range from 260° to 275° C without negatively affecting the capability of the fibre to bond each other.

After the production of the staple in a first step, there is the formation of a fibre web by passing the staple fibres through a carding machine, and by thermal bonding by calendering (calender rolls are employed). The staple fibres can also be thermally bonded by the through air bonding process, where a hot air flow is used to achieve the thermal bonding.

Independently from the specific thermal bonding method employed, the bonding temperatures are preferably within the range from 120° to 160° C, more preferably from 130° to 145° C.

A further embodiment of the present invention relates to thermally bonded articles, in particular non-woven fabrics, produced with the fibres according to the present invention.

The said thermally bonded articles can also be obtained from blends of the fibres of the present invention with conventional polyolefin fibres, in particular made of propylene homopolymers.

Another embodiment of the present invention relates to a composite non-woven fabric. The fabric is made from two or more layers wherein at least one layer is made of the above-mentioned thermal-bonded non-woven fabric. The other layer(s) may be non-woven fabric(s) as well that is/are made of other kind of polymers or polymer compositions.

Thanks to the use of the fibres of the present invention, an improved adhesion among the layers is obtained.

Other thermally bonded composite articles falling in the definition of the present invention are those comprising a non-woven fabric coupled with a polyolefin film, wherein the non-woven fabric is made of or comprises the fibres of the present invention, while the polyolefin film may be made of or comprise the following polyolefins: a random copolymer A of propylene with one or more comonomers selected from α -olefins of formula $\text{CH}_2=\text{CHR}$, wherein R is a $\text{C}_2\text{-C}_8$ alkyl radical, preferably a $\text{C}_2\text{-C}_6$ alkyl radical, and/or a polyolefin B that is selected from polymers or copolymers, and their mixtures, of $\text{CH}_2=\text{CHR}$ olefins where R is a hydrogen atom or a $\text{C}_1\text{-C}_8$ alkyl radical. Another suitable polymer for the film layer is the polyethylene.

The non-woven fabrics of the present invention are particularly useful for hygienic garments, medical drapes, towels, wipers. Typical examples of said composite articles are nappy and other disposable articles.

The coupling between the film and the non-woven fabric can be obtained for instance by heat treatment in a calender or by using adhesives, like hot melts.

The following examples are given to illustrate and not to limit the present invention.

The data relating to the polymeric materials and the fibres of the examples are determined by way of the methods reported below.

- MFR: ISO 1133, 230° C, 2.16 Kg;
- Melting and crystallization temperature: by DSC with a temperature variation of 20° C per minute;
- Ethylene content: by IR spectroscopy;
- Polydispersity Index (PI): measurement of molecular weight distribution of the polymer.

To determine the PI value, the modulus separation at low modulus value, e.g. 500 Pa, is determined at a temperature of 200° C by using a RMS-800 parallel plates rheometer model marketed by Rheometrics (USA), operating at an oscillation frequency which increases from 0.01 rad/second to 100 rad/second. From the modulus separation value, the PI can be derived using the following equation:

$$PI = 54.6 \times (\text{modulus separation})^{-1.76}$$

wherein the modulus separation (MS) is defined as:

$$MS = (\text{frequency at } G' = 500 \text{ Pa}) / (\text{frequency at } G'' = 500 \text{ Pa})$$

wherein G' is the storage modulus and G'' is the low modulus.

- Fractions soluble and insoluble in xylene at 25° C: 2.5 g of polymer are dissolved in 250 ml of xylene at 135° C under agitation. After 20 minutes the solution is allowed to cool to 25° C, still under agitation, and then allowed to settle for 30 minutes. The precipitate is filtered with filter paper, the solution evaporated in nitrogen flow, and the residue dried under vacuum at 80° C until constant weight is reached. Thus one calculates the percent by weight of polymer soluble and insoluble at room temperature (25° C).
- Temperature rising elution fractionation with xylene (TREF): About 1 g of sample is dissolved in 200 mL of o-xylene, stabilized with 0.1 g/L of Irganox® 1010 (pentaerythritol tetrakis 3-(3,5-di-tert-butyl-4-hydroxyphenyl)propanoate). The dissolution temperature is in the range of 125-135° C. The resulting solution is poured off into a column packed with glass beads and subsequently cooled down slowly in 16.5 h to 25° C.

The first fraction is obtained at room temperature eluting with o-xylene. The second

fraction is collected after having raised the column temperature up to 95° C. The polymer component soluble between 25° and 95 °C is collected as a single fraction.

The successive fractions are eluted with o-xylene while the temperature is raised linearly between 95° to 125° C. Each fraction, recovered as a 200 mL solution, is collected at 1° C temperature increments. The polymer fractions are subsequently precipitated with acetone, filtered on a 0.5 µm PTFE filter, dried under vacuum at 70° C and weighted.

- **Titre of fibres:** from a 10 cm long roving, 50 fibres are randomly chosen and weighed. The total weight of the said 50 fibres, expressed in mg, is multiplied by 2, thereby obtaining the titre in dtex.
- **Tenacity and Elongation (at break) of fibres:** from a 500 m roving a 100 mm long segment is cut. From this segment the single fibres to be tested are randomly chosen. Each single fibre to be tested is fixed to the clamps of an Instron dynamometer (model 1122) and tensioned to break with a traction speed of 20 mm/min. for elongations lower than 100% and 50 mm/min for elongations greater than 100%, the initial distance between the clamps being of 20 mm. The ultimate strength (load at break) and the elongation at break are determined.

The Tenacity is derived using the following equation:

$$\text{Tenacity} = \text{Ultimate strength (cN)} \times 10 / \text{Titre (dtex)}$$

- **Bond strength of fibres:** specimens are prepared from a 400 tex roving (method ASTM D 1577-7) 0.4 meter long, made up of continuous fibres. After the roving has been twisted eighty times, the two extremities are united, thus obtaining a product where the two halves of the roving are entwined as in a rope. The thermal bonding is carried out on said specimen using a Bruggel HSC-ETK thermal bonding machine, operating at various plate temperatures (see in the tables) using a clamping pressure of 0.28 MPa and 1 second bonding time. The previously said dynamometer, operated at a traction speed of 2 cm/min, is used to measure the average force required to separate the two halves of the roving which constitute each specimen at the thermal bonding point. The obtained graph shows the force varying from minimum to maximum values (peaks are obtained). The value resulting from averaging out all the minimum and maximum values shown in the graph represents the said average force. The result, expressed in cN, is obtained by averaging out at least eight measurements, and represents the bond strength of the fibres. When non-woven samples are prepared, the bond strength is determined on specimens

20 cm long and 5 cm wide. The 5 cm wide extremities are fixed to the clamps of the dynamometer and tensioned at a clamp speed of 100 mm/min (the initial distance between the clamps being of 10 cm). The maximum force measured in the machine direction (MD) and in the cross direction (CD), with respect to the calendering step, represents the strength of the fibres.

- **Thermal Bonding Index:** calculated as $\sqrt{(Ten_{CD} \times Ten_{MD}) \times (weight / 20)}$, where 20 is the reference weight.

Examples 1 and 2

The polymers are prepared by polymerising propylene and ethylene in the presence of a high yield, highly stereospecific Ziegler-Natta catalyst. The catalyst employed comprises a catalyst component prepared by analogy with example 5 of EP 728 769 but using microspheroidal $MgCl_2 \cdot 1.7 C_2H_5OH$ instead of $MgCl_2 \cdot 2.1 C_2H_5OH$.

Such catalyst component was used with dicyclopentyldimethoxysilane as external donor and with triethylaluminium. The weight ratio $AlEt_3$ /external donor was 30. Other operative conditions and the characteristics of the produced polymers are indicated in Table 1.

The polymers are prepared by polymerising propylene in a first reactor and propylene and ethylene in a second reactor under continuous conditions in a plant comprising a gas phase polymerisation apparatus.

The resulting properties of the polymer compositions are reported in Table 2.

Table 1

Example	1		2	
$AlEt_3$ g/h	90		90	
$AlEt_3$ /solid cat. component g/g	18		20	
Bulk polymerisation	1 st component	2 nd component	1 st component	2 nd component
Temperature °C	72	72	72	70
Split wt%	58	42	60	40
Ethylene content wt%	0	3.57	0	3.75

Notes:

1st component = polymer produced in first polymerisation stage; 2nd component = polymer produced in second polymerisation stage; Split = amount of polymer produced; wt% = % by weight;

Comparative example 1c

Example 1 is repeated except that cyclohexylmethyldimethoxysilane is used as external donor and the polymerisation in the second step is carried out in the same conditions of the first reactor resulting in a homopolymer.

The resulting properties of the polymer are reported in Table 2.

Table 2

Example	1	2	1c
MFR dg/min	12.8	10.8	12
Ethylene content wt%	1.5	1.5	0
Xylene-insoluble fraction wt %	97	96.8	95.3
Polymer fraction eluted between 25-95° C wt%	28.2	28.2	11.7
TREF 25-95° C/xylene soluble ratio	9.4	8.8	2.5
Polydispersity Index	3.3	3.5	3.8
Melting Temperature °C	158.5	157.9	164.4

Examples 3-6

The obtained compositions are spun in a Leonard 25 spinning pilot line having length/diameter ratio of the screw of 25, screw diameter of 25 mm and compression ratio of 1:3. The line is marketed by Costruzioni Meccaniche Leonard-Sumirago (VA).

All spinning tests are made on stabilized, pelletized polymers with two different conventional additive packages formulations.

Spinning tests are carried out with the following conditions: hole diameter=0.4 mm, output=0.4 g/min×hole and mechanical values are measured at 1500 m/min winding speed with stretching ratio 1:1.5.

In Table 3 the properties of the fibres thus obtained are reported.

comparative example 2c

Example 3 is repeated except that the polymer obtained in comparative example 1c is used in the place of the one of example 1.

Table 3 shows that with respect to the comparative ones, the fibres according to the present invention have increased values of the tenacity and particularly increased bonding force also at lower temperature.

Table 3

Example	3	4	5	6	2c
Composition of example	1	1	2	2	1c
Extrusion temperature °C	280	280	280	280	280
Fibre MFR g/10 min	70	71	84	70	80-90
Fibre titre dtex	1.90	2.0	1.95	2.0	2.0
Tenacity cN/tex	22.2	20.6	21.9	25.4	20.0
Elongation at break %	265	220	275	235	285
Bonding force at 150° C cN	635	570	580	645	480
Bonding force at 145° C cN	385	400	360	420	bonding not achieved

Examples 7 and 8 and comparative example 3c

The compositions of example 2 and comparative example 1c are spun in a Leonard 25 spinning pilot line having length/diameter ratio of the screw of 5 and marketed by Costruzioni Meccaniche Leonard-Sumirago (VA).

The spinning conditions are the same as the ones of example 3 except for lower extrusion temperatures as reported in Table 4.

In Table 4 the properties of the fibres thus obtained are reported.

Table 4

Example	7	8	3c
Extrusion temperature °C	270	265	265
Fibre MFR g/10 min	45	25	22
Fibre titre dtex	2.0	2.0	2.0
Tenacity cN/tex	23.9	24.7	20.3
Elongation at break %	275	275	285
Bonding force at 150° C cN	780	370	200

Table 4 shows that with respect to the comparative ones, the fibres according to the present invention maintain a good bonding force value even at lower fiber MFR achieved at lower extrusion temperature whilst the reference fibres have much lower bonding force.

The compositions of this invention allow to obtain high bonding force values with low polymer degradation maintaining good balance tenacity/elongation of the fibre in a wide range of extrusion temperature (265 – 280° C).

Example 9 and comparative example 4c

Staple fibres are prepared as in example 6 and in comparative example 2c excepted that the extrusion temperature is of about 300° C, the output is of 0.345 g/min×hole, winding speed is 1500m/min and stretching ratio is 1:1.3.

Then the staple fibres are subjected to a calendering process for the preparation of a non-woven fabric. The main conditions used in the carding/calendering step are below summarised in Table 5.

Table 5

Carding Speed	m/min	120
Embossed calendering roll temperature	°C	150
Smooth calendering roll temperature	°C	139

In Table 6 same data relating to the staple fibres and the non-woven fabric thus produced are reported. The Edana Standard Method is used to test the properties of the non-woven fabric.

Table 6

Example		4c	9
Features of the fibre			
Average filament titer	dtex	2.10	2.16
Fibre MFR	g/10'	45	38
Features of the non-woven fabric			
Weight	g/m ²	20	20
Tenacity CD	N/5cm	8.7	12
Tenacity MD	N/5cm	38.0	37.0
Elongation at break CD	%	45	42
Elongation at break MD	%	38	35
Thermal Bonding Index	N/5cm	18.2	21.1

Table 6 shows that the non-woven fabric according to the present invention has a 38% increase of cross directional tenacity in comparison with the comparative non-woven fabric and also a good processability.

25. Sep. 2002

Claims

1. A fibre for thermal bonding comprising a propylene polymer composition having an MFR"L" value from 4 to 20 g/10 min, and being selected from:
 - i) a crystalline propylene random polymer containing at least 0.8% by weight of ethylene and optionally one or more C₄-C₁₀ α -olefins; the said polymer having a melting temperature of 155° C or higher, a content of fraction soluble in xylene at room temperature lower than 5% by weight, a value of the ratio of the polymer fraction collected at the temperature range from 25° to 95°C by temperature rising elution fractionation with xylene (TREF) to the xylene soluble fraction, higher than 8; and
 - ii) crystalline propylene polymer blend having a melting temperature of 153° C or higher, a content of fraction soluble in xylene at room temperature lower than 10% by weight; the said blend containing at least 0.64 wt% of ethylene recurring unit and comprising (percent by weight):
 - I) 20-80%, preferably from 30-70%, of a crystalline propylene homopolymer and/or crystalline propylene random copolymer containing up to 1.5% by weight of ethylene; and
 - II) 20-80%, preferably from 30-70%, of a crystalline random copolymer selected from:
 - IIa) a copolymer of propylene with 0.8 to 9% by weight of ethylene; provided that the difference in the ethylene content between polymer (I) and polymer (IIa) be at least 0.8 percentage unit with respect to the weight of the (co)polymer concerned; and
 - IIb) a copolymer of propylene with 1.5 to 18% by weight of a C₄-C₁₀ α -olefin and optionally ethylene; provided that the difference in the comonomer content between polymer (I) and polymer (IIb) be at least 1.5 percentage units with respect to the weight of the (co)polymer concerned; and
 - IIc) a mixture of copolymer (IIa) and copolymer (IIb).
2. The fibre of claim 1 wherein polymer blend (ii) has a melting temperature of 155° C or higher, a content of fraction soluble in xylene at room temperature lower than 5% by weight and a value of the ratio of the polymer fraction collected at the temperature range from 25° to 95° C by TREF to the xylene soluble fraction higher than 8; the said blend

containing at least 0.64 wt% of ethylene recurring unit and comprising (percent by weight):

- I) 20-80%, preferably from 30-70%, of a crystalline propylene homopolymer and/or crystalline propylene random copolymer containing up to 1.5% by weight of ethylene; and
- II) 20-80%, preferably from 30-70%, of a crystalline random copolymer selected from:
 - IIa) a copolymer of propylene with 0.8 to 5% by weight of ethylene; provided that the difference in the ethylene content between polymer (I) and polymer (IIa) be at least 0.8 percentage unit with respect to the weight of the (co)polymer concerned;
 - IIb) a copolymer of propylene with 1.5 to 12% by weight of a C₄-C₁₀ α -olefin and optionally ethylene; provided that the difference in the comonomer content between polymer (I) and polymer (IIb) be at least 1.5 percentage units with respect to the weight of the (co)polymer concerned; and
 - IIc) a mixture of copolymer (IIa) and copolymer (IIb).
3. The fibre of claims 1 and 2 wherein the polymer material has MFRL values from 6 to 15 g/10 min.
4. The fibre of claims 1 to 3 wherein the difference in the ethylene content between polymer (I) and polymer (IIa) is at least 1 percentage unit with respect to the weight of the (co)polymer concerned.
5. The fibre of claims 1-4 having a value of bonding force at 150° C of at least 300 cN.
6. The fibre of claims 5 and 6 obtainable by a spinning process wherein the composition is subjected to an extrusion temperature of 275° C or less.
7. The fibre of claim 5 having a bonding force value of 300 to 800 cN and a MFR value of 50 g/10 min or less and obtainable by a spinning process wherein the composition is subjected to an extrusion temperature of 275° C or less.
8. The fibre of claims 6-7 wherein the extrusion temperature ranges from 260° to 275° C.
9. A melt spin process for the production of the fibres according to claims 1-4 characterised in that it is subjected to the process a propylene polymer composition having an MFR"L" value from 4 to 20 g/10 min and being selected from:
 - i) a crystalline propylene random polymer containing at least 0.8% by weight of ethylene and optionally one or more C₄-C₁₀ α -olefins; the said polymer having a

melting temperature of 155° C or higher, a content of fraction soluble in xylene at room temperature lower than 5% by weight, a value of the ratio of the polymer fraction collected at the temperature range from 25° to 95° C by TREF to the xylene soluble fraction, higher than 8; and

ii) crystalline propylene polymer blend having a melting temperature of at least 153° C or higher, a content of fraction soluble in xylene at room temperature lower than 9% by weight; the said blend containing at least 0.64 wt% of ethylene recurring unit and comprising (percent by weight):

I) 20-80%, preferably from 30-70%, of a crystalline propylene homopolymer and/or crystalline propylene random copolymer containing up to 1.5% by weight of ethylene; and:

II) 20-80%, preferably from 30-70%, of a crystalline random copolymer selected from:

IIa) a copolymer of propylene with 0.8 to 9% by weight of ethylene; provided that the difference in the ethylene content between polymer (I) and polymer (IIa) be at least 0.8 percentage unit with respect to the weight of the (co)polymer concerned;

IIb) a copolymer of propylene with 1.5 to 18% by weight of a C₄-C₁₀ α -olefin and optionally ethylene; provided that the difference in the comonomer content between polymer (I) and polymer (IIb) be at least 1.5 percentage units with respect to the weight of the (co)polymer concerned; and

IIc) a mixture of copolymer (IIa) and copolymer (IIb).

10. The process of claim 9 wherein polymer blend (ii) has a melting temperature of 155° C or higher, a content of fraction soluble in xylene at room temperature lower than 5% by weight, a value of the ratio of the polymer fraction collected at the temperature range from 25° to 95° C by TREF to the xylene soluble fraction, higher than 8; the said blend containing at least 0.64 wt% of ethylene recurring unit and comprising (percent by weight):

I) 20-80%, preferably from 30-70%, of a crystalline propylene homopolymer and/or crystalline propylene random copolymer containing up to 1.5% by weight of ethylene; and

II) 20-80%, preferably from 30-70%, of a crystalline random copolymer selected from:

- IIa) a copolymer of propylene with 0.8 to 5% by weight of ethylene; provided that the difference in the ethylene content between polymer (I) and polymer (IIa) be at least 0.8 percentage unit with respect to the weight of the (co)polymer concerned;
- IIb) a copolymer of propylene with 1.5 to 12% by weight of a C₄-C₁₀ α -olefin and optionally ethylene; provided that the difference in the comonomer content between polymer (I) and polymer (IIb) be at least 1.5 percentage units with respect to the weight of the (co)polymer concerned; and
- IIc) a mixture of copolymer (IIa) and copolymer (IIb).
11. The process of claims 9 and 10 wherein the composition is extruded at a temperature of 275° C or lower.
 12. The process of claim 11 wherein the composition is extruded at a temperature ranging from 260° to 275° C.
 13. A thermally bonded non-woven fabric comprising the fibres of claims 1-8.
 14. A composite non-woven fabric comprising two or more layers wherein at least one layer is made of the thermal-bonded non-woven fabric of claim 13.
 15. A process for the production of non-woven fabric of claim 13, wherein the fibres of claims 1 to 8 are subjected to thermalbonding.
 16. A crystalline propylene polymer blend having an MFR"L" value from 4 to 20 g/10 and an ethylene content of at least 0.64 wt% and comprising (percent by weight):
 - I) 20-80%, preferably from 30-70%, of a crystalline propylene homopolymer or crystalline propylene random copolymer containing up to 1.5% by weight of ethylene; and
 - II) 20-80%, preferably from 30-70%, of a crystalline random copolymer of propylene with higher than 5 to 9% by weight of ethylene;the said blend having a melting temperature of 153° C or higher and a content of fraction soluble in xylene at room temperature lower than 9% by weight.
 17. The blend of claim 16 having MFRL values from 6 to 15 g/10 min.
 18. A process for the polymerisation the crystalline propylene polymer blend of claims 16 and 17 carried out in at least two separate subsequent stages, wherein in at least two polymerisation stages the relevant monomers are polymerised to form polymer (I) and in the other stage(s) the relevant monomers are polymerised to form polymer (II),

operating in each stage, except the first step, in the presence of the polymer formed and the catalyst used in the preceding stage.

25. Sep. 2002

Abstract

A fibre comprising a propylene polymer composition having an MFR"L" value from 4 to 20 g/10 min. The said composition is selected from (i) a crystalline propylene random polymer containing at least 0.8% by weight of ethylene and optionally one or more C₄-C₁₀ α -olefins; the said polymer having a melting temperature of 155° C or higher, a content of fraction soluble in xylene at room temperature lower than 5% by weight, a value of the ratio of the polymer fraction collected at the temperature range from 25° to 95° C by temperature rising elution fractionation with xylene to the xylene soluble fraction, higher than 8; and (ii) a crystalline propylene polymer blend having a melting temperature of 153° C or higher, a content of fraction soluble in xylene at room temperature lower than 10% by weight; the said blend containing at least 0.64 wt% of ethylene recurring unit and comprising (I) 20-80 wt% of a crystalline propylene homopolymer and/or crystalline propylene random copolymer containing up to 1.5% by weight of ethylene; and (II) 20-80% wt of a crystalline random copolymer of propylene with ethylene or a C₄-C₁₀ α -olefin.

A polymer blend having an MFR"L" value from 4 to 20 g/10 min, an ethylene content of at least 0.64 wt% and comprising (A) 20-80 wt% of a crystalline propylene homopolymer or crystalline propylene random copolymer containing up to 1.5% by weight of ethylene; and (B) 20-80 wt% of a crystalline random copolymer of propylene with higher than 5 to 9% of ethylene.

Non-woven fabrics that are prepared with the said fibres are useful for hygienic applications.
